Improving Backtracking

- * What variable to assign next?
- * What order to try the domain values?
- * What inference can be made to detect failure early?
- * Can we take advantage of the problem structure?

Improving Backtracking

- * What variable to assign next?
- * What order to try the domain values?
- * What inference can be made to detect failure early?
- * Can we take advantage of the problem structure?

What var to do next?

- * **Simplest**: some fixed order, or random
- * **Better idea**: choose the most constrained variable as the next one to assign so it doesn't run out of options

Minimum Remaining Values (MRV)

- * Choose var with the fewest legal values

Minimum Remaining Values (MRV)

- * Choose var with the fewest legal values

Minimum Remaining Values (MRV)

- * Choose var with the fewest legal values

Degree Heuristic

- * Tie breaker for MRV
- * Choose var with most constraints on remaining variables

Improving Backtracking

- * What variable to assign next?
- * What order to try the domain values?
- * What inference can be made to detect failure early?
- * Can we take advantage of the problem structure?

Least Constraining Value

- * Given a variable, choose value that rules out the least values in remaining vars

Improving Backtracking

- * Variable ordering -- **fail first**, to minimize nodes in the search tree
- * Value ordering -- **fail last**, we only need one solution so keep options open
- * Can we **interleave search and inference** to narrow our choices even further?

Improving Backtracking

- * What variable to assign next?
- * What order to try the domain values?
- * What inference can be made to detect failure early?
- * Can we take advantage of the problem structure?

Forward Checking

- * Track remaining legal vals for vars, backtrack when any is empty

Forward Checking

- * Track remaining legal vals for vars, backtrack when any is empty

Forward Checking

- * Track remaining legal vals for vars, backtrack when any is empty

WA	NT	Q	NSW	V	SA	T

Forward Checking

- * Keep track of remaining legal vals for vars, terminate and backtrack when any is empty
- * MRV + Forward Checking...
 - * FC is efficient way to compute info that the MRV heuristic needs

Constraint Propagation

- * Can stop a branch even earlier by propagating constraints and values
- * After deleting neighbors run constraints

<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>
<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>
<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>	<div><div></div><div></div><div></div></div>

NT and *SA* cannot both be blue!

Constraint Propagation

- * Use the constraints to limit the domain values of your variables
- * Any time you set a variable, propagate that decision to the domains of all your other variables

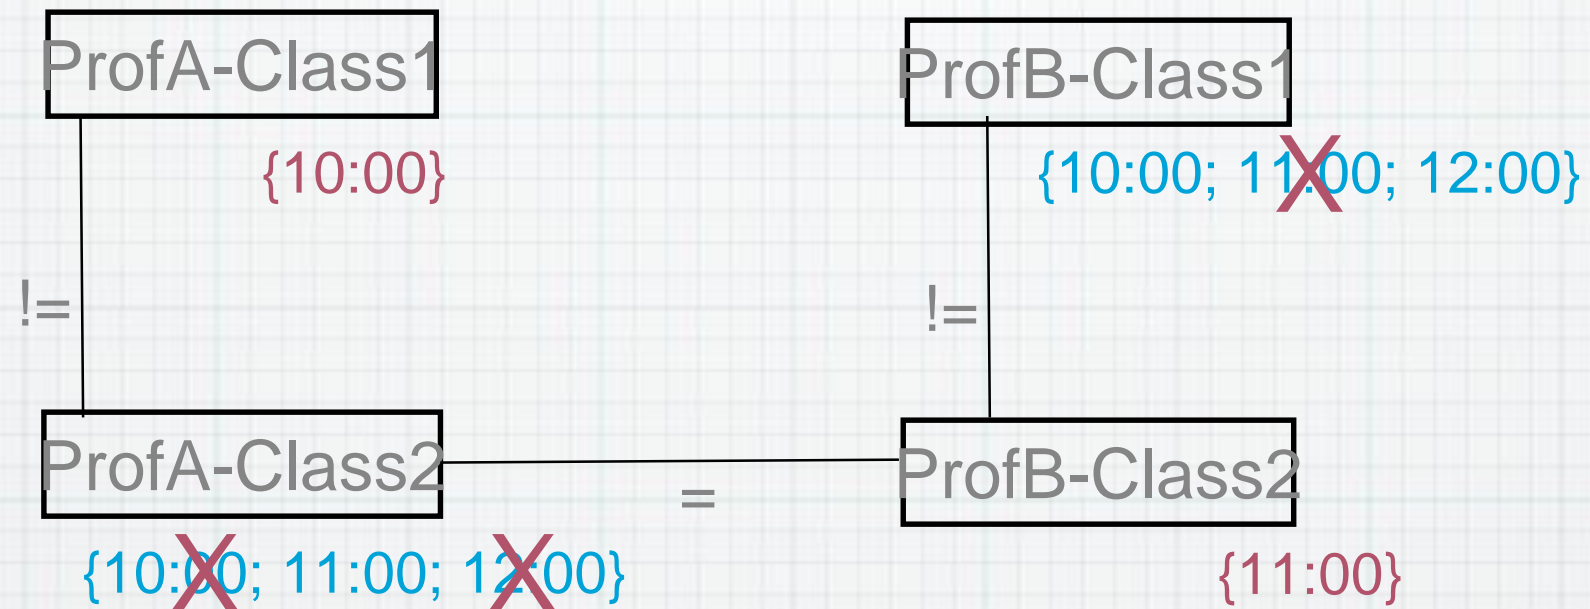

Constraint Propagation

Constraint Propagation

Constraint Propagation

Constraint Propagation

Arc Consistency

Simplest form of propagation makes each arc **consistent**

$X \rightarrow Y$ is consistent iff
for **every** value x of X there is **some** allowed y

Arc Consistency

Simplest form of propagation makes each arc **consistent**

$X \rightarrow Y$ is consistent iff
for **every** value x of X there is **some** allowed y

Arc Consistency

Simplest form of propagation makes each arc **consistent**

$X \rightarrow Y$ is consistent iff
for **every** value x of X there is **some** allowed y

Arc Consistency

Simplest form of propagation makes each arc **consistent**

$X \rightarrow Y$ is consistent iff
for **every** value x of X there is **some** allowed y

If X loses a value, neighbors of X need to be rechecked

Arc Consistency

Simplest form of propagation makes each arc **consistent**

$X \rightarrow Y$ is consistent iff
for **every** value x of X there is **some** allowed y

If X loses a value, neighbors of X need to be rechecked

Arc consistency detects failure earlier than forward checking

Can be run as a preprocessor or after each assignment

Arc Consistency

function AC-3(*csp*) **returns** the CSP, possibly with reduced domains

inputs: *csp*, a binary CSP with variables $\{X_1, X_2, \dots, X_n\}$

local variables: *queue*, a queue of arcs, initially all the arcs in *csp*

while *queue* is not empty **do**

$(X_i, X_j) \leftarrow \text{REMOVE-FIRST}(\textit{queue})$

if REMOVE-INCONSISTENT-VALUES(X_i, X_j) **then**

for each X_k **in** NEIGHBORS[X_i] **do**

 add (X_k, X_i) to *queue*

function REMOVE-INCONSISTENT-VALUES(X_i, X_j) **returns** true iff succeeds

removed \leftarrow false

for each x **in** DOMAIN[X_i] **do**

if no value y in DOMAIN[X_j] allows (x, y) to satisfy the constraint $X_i \leftrightarrow X_j$

then delete x from DOMAIN[X_i]; *removed* \leftarrow true

return *removed*

$O(n^2d^3)$, can be reduced to $O(n^2d^2)$ (but detecting **all** is NP-hard)

5	3			7				
6			1	9	5			
	9	8					6	
8				6				3
4			8		3			1
7				2				6
	6					2	8	
			4	1	9			5
				8			7	9

Domain: {1,2,3,4,5,6,7,8,9}

Propagate Box constraint

{1,2,3,4,5 7,8,9}

Propagate Row constraint

{ 2,3 7,8 }

Propagate Col constraint

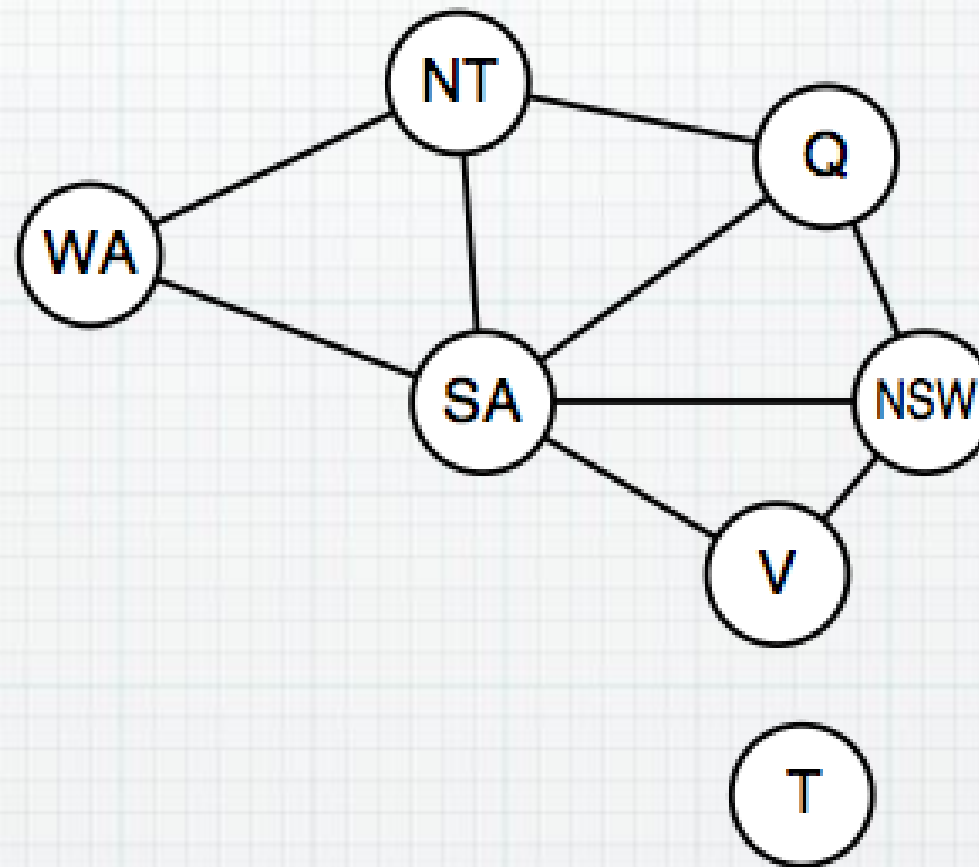

{ 2,3 7 }

For Sudoku, you just propagate constraints, setting values as their domains have only one option

Improving Backtracking

- * What variable to assign next?
- * What order to try the domain values?
- * What inference can be made to detect failure early?
- * Can we take advantage of the problem structure?

Problem Structure

Tasmania and mainland are **independent subproblems**

Identifiable as **connected components** of constraint graph

Tree-structured CSPs

Theorem: if the constraint graph has no loops, the CSP can be solved in $O(nd^2)$ time

Compare to general CSPs, where worst-case time is $O(d^n)$

Solving Tree CSPs

1. Choose a variable as root, order variables from root to leaves such that every node's parent precedes it in the ordering

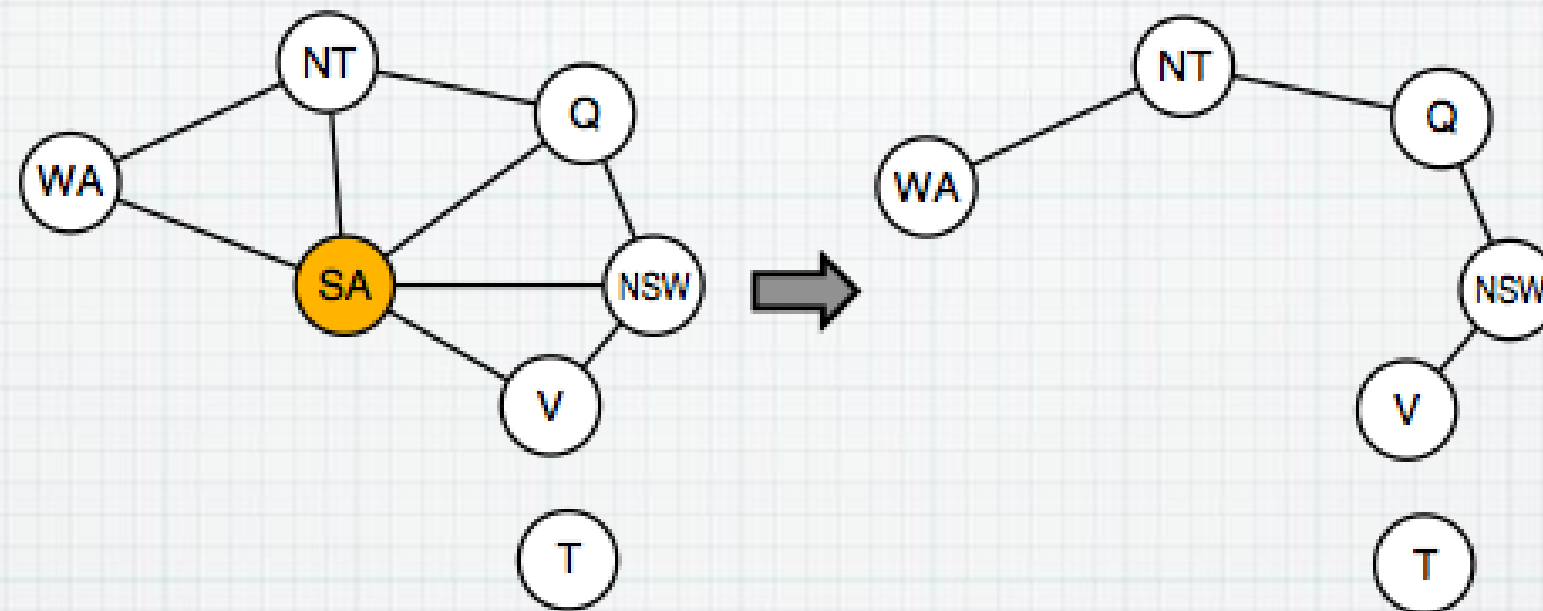

2. For j from n down to 2, apply $\text{REMOVEINCONSISTENT}(\text{Parent}(X_j), X_j)$
3. For j from 1 to n , assign X_j consistently with $\text{Parent}(X_j)$

Wow, trees are easy! Let's make everything a tree...

Nearly Trees

Conditioning: instantiate a variable, prune its neighbors' domains

Cutset conditioning: instantiate (in all ways) a set of variables such that the remaining constraint graph is a tree

Cutset size $c \Rightarrow$ runtime $O(d^c \cdot (n - c)d^2)$, very fast for small c

Summary

- * CSP are special problem representing states=variables, goals=constraints
- * Backtracking = DFS assign 1 var/node
- * Variable ordering and Value selection heuristics help significantly
- * Constraint propagation prevents assignments that lead to later failure
- * Problem structure helps, Tree CSPs can be solved in linear time.
